The Role of Carbon Capture and Storage (CCS) in Tackling Climate Change

Nick Mabey, E3G

September 2008
Outline

- Delivering Climate Security

- The Economics of Transformation

- Managing Climate Risks
  - Avoiding high carbon lock-in
  - Delivering energy and climate security
  - Managing policy failure

- Developing CCS as a critical low carbon option
Past GHG emissions will result in 1.6°C warming. Business as Usual will result in a rise of up to 6.5°C by 2100.

Source: IPCC (2007)
Global temperature rise above 2°C has been seen as a threshold for greatly increased damages.

Source: Vattenfall (2007); IPCC WG II (2007)
IPCC AR4 Finds Greater Risks

Preserving climate security means avoiding climate tipping points

IPCC/Stern analysis did not include many of the most extreme impacts of climate change

• High impact scenarios: Atlantic conveyor slowdown; increased storm activity; monsoon variation;

• Cost of social instability and conflict

• Irreversible impacts (all accelerating): glacial melting; icesheet melting rates; ocean acidification

• Runaway climate change: Amazon forest dieback; tundra melt; release of methane hydrates;

Stern acknowledges he underestimated the cost of climate change. Real issue is how we avoid passing these tipping points

• Developing CCS as a critical low carbon option
There is less time to avoid disastrous climate change: peak in global emissions in next 10 years

(M. Meinshausen, PIK)
A 2C future means Developed Countries emissions falling 20-30% by 2020 and 60-80% by 2050

This aggressive scenario gives a 50% chance of avoiding a 2C temperature rise

Source: European Commission EPRG January 2007
This requires delivery of a lot of efficiency and new low carbon generation in the next 20 years.

**CO2 Emissions in the 450 Stabilisation Case**

**Share of Cumulative Power-Generation Investment by Technology, 2006-2030**

Source: IEA, WEO (2007)
Transformation needed in a small number of large developed and developing country emitters

Twenty-five countries (counting the EU as one) are responsible for 83% of global greenhouse gas emissions

Source: CAIT.2007

Source: WRI CAIT Energy Information Administration Reference Scenario, Energy emissions only
The implied investment shifts in these scenarios are very dramatic

Climate Change is a unique challenge to drive global change in markets and technology towards a public good goal inside a specific timescale (outside WWII and Cold War).

Post 2012 framework needs to target three core activities:

- **Investment**: consistent signals to investors to move on-going energy system investment towards low carbon alternatives.

- **Innovation**: produce sufficient “market pull” to generate radical investment in innovation in the next generation of low carbon technologies, services and businesses.

- **Institutions**: redesign the market, regulatory and business models currently shaping the energy system so they efficiently and effectively drive low carbon investment, and are increasingly sensitive to carbon price signals.

Very weak understanding of what is a robust system of incentives and institutions to drive the transition to a low carbon economy
Outline

• The Economics of Transformation

• Managing Climate Risks
  – Avoiding high carbon lock-in
  – Delivering energy and climate security
  – Managing policy failure

• Developing CCS as a critical low carbon option
Managing Climate Change Risk

- High risk of catastrophic climate change if miss low emission paths

- Large simultaneous shift to high efficiency and low carbon power needed in developed and major developing countries

- Mechanisms and technologies for achieving this transformation very underdeveloped

Need to develop a risk management approach to climate change - not a cost-optimisation frame

Aging infrastructure means significant new energy investment

Source: IEA, 2006; Euroelectric 2007
Even in Europe more than half of current generation capacity will need to be replaced by 2030

- IEA 2005-2030 the total new capacity in EU will be 862 GW, additional installed capacity is 395 GW; 61% of current capacity.

- Eurelectric 822 GW of new power stations replacement of old capacity (439 GW).

- In 2030-2050 new investment is estimated at 605 TW and decommissioning at 470 GW
Developing countries are also investing in major power infrastructure

Cumulative Power-Sector Investment by Region in the Reference Scenario, 2005-2030

- China alone needs to invest about $3.7 trillion - 18% of the world total.
- Russia and other transition economies account for 9% of total world investment.

Source: IEA, WEO 2006
Lock-in of unabated coal power and standard power infrastructure

- Business as usual development would see lock-in to a new generation of coal and conventional power infrastructure

- Even with CCS unless power systems are made truly CCS-compatible now – location; technologies; supply chains – retrofit is highly unlikely

- Lowest risk to climate security would be to have a moratorium on new coal generation without CCS; first impact would be to drive a global dash to gas.
Outline

• Delivering Climate Security

• The Economics of Transformation

• Managing Climate Risks
  – Avoiding high carbon lock-in
  – Delivering energy and climate security
  – Managing policy failure

• Developing CCS as a critical low carbon option
Energy and Climate Security are public goods; markets will not automatically give right signals to shift major investment

- Recent fossil fuel price increases dwarf equilibrium carbon price in Stern Review/IEA etc but are not leading to carbon-free economy

- Price rises and energy security are driving investment in climate instability:
  - rapid rise in coal power investment - outside US
  - coal to liquids investment in US and China
  - large increase in carbon inefficient biofuels

- Impact on energy efficiency of high energy prices has been very slow, even in transport sector

Need coherent, clear and effective policy signals to drive investment to deliver energy and climate security together
Most major countries have good reasons for using indigenous coal and avoiding gas

- **Europe**: fear of dependency on Russia and North Africa/Iran; Georgia effect!

- **India**: Pakistan/US block to Iranian gas; tensions with Myanmar/Bangladesh/Nepal on gas and hydro access

- **China**: reluctance to rely on Russia – limited supplies from Central Asia and Myanmar.

- **US**: major gas supplies from Canada plus indigenous sources
Any credible strategy must deliver energy and climate security

- In the short term energy security will always trump climate security

- Strong policy on coal moratorium is good for investment in CCS and other alternatives, but raises fears of gas dependence

- Without advances in solar technology countries such as China and India have few alternatives

- "Carbon Catch 22" biases towards existing technologies as policy makers find it hard to give credible incentives for alternatives at scale.

43% reduction through energy efficiency; 19% from CCS

Source: Adapted from IEA ETP 2008 by Froggatt and Viswanath, 2008
Risk to these scenarios are high and hedging strategies are needed

- Efficiency is notoriously hard to deliver at pace in all countries without punitive price signals
- Demand growth may be higher - especially in Asian transport markets
- Lack of delivery on alternative biofuels would place more pressure on low carbon power generation

Need to plan for policy failure leading to higher demands for low carbon electricity
Outline

- Delivering Climate Security
- The Economics of Transformation
- Managing Climate Risks
  - Avoiding high carbon lock-in
  - Delivering energy and climate security
  - Managing policy failure
- Developing CCS as a critical low carbon option
The case for developing the CCS option as quickly as possible

- Need to have a high probability for avoiding climate change tipping points and have hedges against policy failures

- Investment dynamics and energy security imperatives mean that large scale new coal build is very likely globally

- Without CCS as a viable power option soon these investments will lock-in climate instability into the future; must avoid “CCS Ready” camouflage

- All radical abatement trajectories assume early deployment of CCS. If CCS is not technically, geologically or economically feasible at large scale need to know quickly in order to develop “Plan B”

**Climate risks are too high not to take CCS seriously**
Constructing a CCS strategy

- Whether you “believe” in CCS or not – it is critical to have an early answer to CCS feasibility and costs.

- First step is to avoid lock-in to unabated coal: moratorium in developed countries; carbon capture compatible in developing countries

- Second step is global demonstration programme of at least 20 full scale plants by 2015. Public funded to ensure technology and geographic spread – and public IPR generation.

- Third step is regulatory and financial incentives for technology diffusion and deployment from 2015 onwards

Aim is not to pick winners- but to ensure there are enough winners available to avoid catastrophic climate change
